1. Shown below are two single stage common base amplifiers using a NPN BJT as the active amplifying devices. Circuit 1 is biased with an ideal current source while circuit two is biased with a two transistor current source. The dc power supply voltages are $V^+ = 15\, \text{V}$ and $V^- = -15\, \text{V}$. It is given that $C_1 = 10\, \mu\text{F}$, $C_2 = 22\, \mu\text{F}$, $C_E = 330\, \mu\text{F}$, $R_L = 10\, \text{k}\Omega$, $R_B = 51\, \text{k}\Omega$, and $R_C = 6.8\, \text{k}\Omega$. Design Circuit 1 so that the magnitude of the midband voltage gain is $10^3$ and the circuit clips symmetrically. Design Circuit 2 so that it has the same specifications as Circuit 1. For the calculations assume that $\beta = \infty$ for all the transistors and for the simulations use the value below.

2. For each circuit, use National Instruments SPICE Multisim to determine:
   - the dc operating point of the circuit, viz. the dc voltage at each terminal of the transistor and the current flowing into the collector and base leads and out of the emitter. (DC Operating Point or OP analysis)
   - the small signal ac voltage gain, viz. a plot of the gain, $A_v$ versus frequency where the frequency range is from $10\, \text{Hz}$ to $100\, \text{MHz}$. (AC Analysis)
   - plot of the output voltage versus time for 2 cycles of the input for an input signal a sine wave with a frequency of $1\, \text{kHz}$ and a peak values for which the output is not clipped, is on the verge of clipping, and significantly clipped (hard clipping). (Transient Analysis)
   - plot of the output voltage versus frequency for a frequency span from dc to $10\, \text{kHz}$, viz. the spectra of the output with an input signal a sine wave with a frequency of $1\, \text{kHz}$ and a peak value which causes the output to clip. Plot the output voltage on a log scale. Determine the THD (Fourier Analysis)
   - plot the noise spectral density at the output (noise analysis). Also determine the total noise at the output.

   Assume that the SPICE parameters for the NPN BJT are: saturation current, $6.734\, \text{fA}$; forward beta, 100; Early voltage, $170\, \text{V}$, zero-bias base collector capacitance, $3.638\, \text{pF}$; forward transit time, $301.2\, \text{ps}$, and base spreading resistance, $10\, \Omega$.

3. Verify the SPICE solution for the above with a hand calculation using the parameters given for the SPICE simulation. Calculate the dc operating point, mid-band small signal voltage gain, and positive and negative clipping levels.
